

7.2.s. Summary

Generalizations will be expressed symbolically using **quantifiers**, operations that take predicates as input and yield sentences as output. More specifically, we will use two **universal quantifiers** both written using the symbol \forall (for all). The sentences formed using these quantifiers will be called **universals**. The two quantifiers are the **restricted universal quantifier**, which applies to a pair of predicates to form a sentence, and the **unrestricted universal quantifier**, which applies to a single predicate. We will apply quantifiers only to abstracts. Since any pair of abstracts can be written in the form $\lambda x (...x...)$ and $\lambda x (---x---)$ using the same variable, we can abbreviate universal sentences as $(\forall x: ...x...) ---x---$ and $\forall x ---x---$. These may be put into English notation as **Everything, x, such that p_x is such that θ_x and Everything, x, is such that θ_x** . (Here the word *thing* is used as a **dummy restriction** that merely provides a hook for the relative clause.) The component expressions $...x...$ and $---x---$, the **restricting** and **quantified** formulas of the universal, will not ordinarily be sentences in the strictest sense because they will contain **free occurrences** of the variable x . (The exceptions are the bodies of **vacuous** abstracts expressing predicates with a constant value.) Such expressions are included in the broader class of formulas, among which **sentences** are distinguished as **closed** formulas. Terms, too, can be classified as **open** or closed. A restricted universal says that the extension of the first predicate to which it is applied, the **restricting predicate**, is included in the extension of the second, the **quantified predicate**—i.e., it says that the second expresses a property that is at least as general as that expressed by the first. The unrestricted quantifier says that the quantified predicate to which it applies is **universal**, that it is a predicate that expresses a fully general property. An unrestricted universal sentence can be restated as a restricted universal whose domain predicate is universal, and a restricted universal can be **restated** as an unrestricted universal provided we make the attribute predicate conditional on the domain predicate.

An English generalization may be analyzed symbolically by using restricting and quantified predicates that capture its domain and attribute. If its domain consists of all reference values, an

unrestricted universal may be used and we need only capture its attribute. In an affirmative generalization, the attribute predicate will be the quantified predicate of the English generalization while in a negative generalization it will be the negation of the quantified predicate. A formula applying the restricting predicate can be formed from the class indicator C by using the form x *is a* C, adding negation if the generalization is complementary. (However, we start with x *is a person* in the case of *everyone* and *no one*.) Bounds and exceptions may be captured by conjoining predicates of the same form, negated in the case of exceptions. The phrase *all and only* is used to express a conjunction of affirmative direct and negative complementary generalizations; but a generalization of this sort can be analyzed also by an unrestricted universal applying to a biconditional predicate because the two generalizations it implies can be expressed using an *if*-conditional and an *only-if*-conditional, respectively.
